

Lasting Connections

WELDING SOLUTIONS FOR OIL & GAS DOWNSTREAM

LASTING CONNECTIONS

As a pioneer in innovative welding consumables, Böhler Welding offers a unique product portfolio for joint welding worldwide. More than 2000 products are adapted continuously to the current industry specifications and customer requirements, certified by well-respected institutes and thus approved for the most demanding welding applications.

Our customers benefit from a partner with

- » the highest expertise in joining, rendering the best application support globally available
- » specialized and best in class product solutions for their local and global challenges
- » an absolute focus on customer needs and their success
- » a worldwide presence through factories, offices and distributors

SPECIALIZED WELDING CONSUMABLES FOR THE OIL & GAS DOWNSTREAM INDUSTRY

Böhler Welding has more than 30 years of experience in the production of welding consumables for critical process equipment (CPE) and furnace tubes for demanding applications. Amongst others, we provide best-in-class CrMo and CrMoV welding consumables, fulfilling and often exceeding the requirements of relevant API recommended practices, the applicable codes, as well as the specifications used in the industry. They feature excellent toughness at low temperature, high resistance to temper embrittlement, creep resistance and all the needed mechanical properties.

We supply weld overlay solutions for a wide number of alloys, including innovative single layer and high speed strip cladding, with proven corrosion resistance and disbonding properties. Last but not least we provide well referenced solutions for centrifugal casting tubes, with filler metals matching the base material grades.

Oil and gas play an important role in the future global energy supply model. However, the emergence of new and unconventional sources of oil and gas will change the land-scape with regard to extraction and processing in many significant ways. Upstream Oil & Gas refers to the search for crude oil and natural gas, followed by their recovery and production. This segment is also referred to as the Exploration and Production (E&P) sector; it includes the search for potential underground or sub-sea oil and gas

fields, the drilling of exploratory wells, and the subsequent drilling and operation of the wells that recover and bring the crude oil and/or raw natural gas to the surface. Downstream Oil & Gas refers to the refining and processing of the extracted oil and gas from both conventional and unconventional resources. This segment is also referred to as hydrocarbon processing and includes refineries, natural gas processing plants, Olefins and Aromatics as well as Methanol plants.

voestalpine Böhler Welding provides solutions driven by its high-quality welding consumables for safe, efficient, and cost-effective operation of upstream, midstream, and downstream facilities and equipment to these segments worldwide. These products are supplied by regional manufacturing, development, sales, and support units under a range of products that are recognized worldwide.

OIL & GAS DOWNSTREAM – WALKING ON THE EDGE OF STEEL LIMITS

Global demand for fuel products is increasing. The quality of petroleum compounds, such as crude oil or natural gas that is extracted in different geographical locations varies, and extra-heavy oil is playing a more significant role than in the past. More sources of unconventional oil and gas from oil sands and shale have been recently explored, and they have been receiving a great deal of attention. Today, environmental regulations with regard to fuels and petrochemical products have become more stringent.

All these variables put together a complicated function in front of the oil and gas "super-majors" to make top-quality products especially from extra-heavy feedstock, and still achieve a healthy margin. As shown in this road map derived from the key drivers, the main challenge in setting defined objectives and developing solutions is to maintain the integrity of the process component while dealing with a wide range of damage mechanisms.

These additional damage mechanisms are either related to the unconventional feedstock or enhanced service conditions. In recent years, steel manufacturers have been developing better steel grades to withstand such service conditions. One must take into consideration that steel products need to be welded or cladded by weldoverlay; it is at this point that customers face the main welding challenges.

A good example is development of vanadium-enhanced Cr-Mo steels, which require special weld fabrication expertise. Welding consumables may seem to be a very small part of this industry, but almost all oil and gas downstream experts confirm that welding and welding technologies are the main drivers in the development of optimized process reactors and furnaces. The requirements for welding consumables in the downstream segment are generally considered to be more stringent than the conventional standard requirements for the same grades in other fields.

In the following, we will summarize the most important damage mechanisms in each of the three main plants. We will also be providing information about two of the major challenges: fabrication of hydroprocessing reactors (Page 8) and reforming / cracking furnaces (Page 13).

Key Drivers	Objectives	Process Solutions
Environmental Regulations	 Cleaner Fuel Lower CO₂ Emission Lower Sulfur 	» Hydrotreating» Refinery Upgrade
Refining Market Pressure	» Flexibility on Feedstock» Increase the Yield» High Yield from Heavy Crude	 Conversion Units High Nelson Complexity Conversion Units Gas Processing
Unconventional Oil/Gas	 » Shale Gas in the Value chain » Reasonable Yield from Oil Sands » Utilize Extra Sour Gas » Gas to Liquid Fuel 	» Conversion Units » Gas Processing » GTL
Operational Costs	» Optimizing Energy Consumption» Maximize Component Lifetime» Minimize M&R Costs	» Wider use of CRA» Wider use Cladding

OIL REFINERIES

Hydrocarbon molecules come in many different sizes and shapes that generally depend on the quality of the crude oil. In an oil refinery, five different process categories are utilized to achieve both a higher yield and cleaner fuel.

Table A: Alloy choices for major refinery components

- » Fractionating hydrocarbon molecules by size, e.g., in a crude distillation unit
- » Cracking larger molecules into smaller ones, e.g., in a fluid catalytic cracking unit or a hydrocracking unit
- » Combining smaller hydrocarbon molecules into larger molecules, e.g., in an alkylation unit
- » Changing the molecule shapes, e.g., in a catalytic reforming unit
- » Hydrotreating units are also needed to reduce sulfur, aromatics, nitrogen, oxygen, and metals while enhancing the combustion quality, density, and smoke point of fuels

Depending on the process, its feedstock and operating conditions, various damage mechanisms can pose a threat to the life cycle of a refinery, to equipment integrity, and to plant safety. Many of these damage mechanisms can directly or indirectly relate the quality of welding consumables and welding condition. Some of the major damage mechanisms are listed in this text.

The choices regarding the base material used for critical process equipment in a refinery as well as for weld-overlay cladding are limited. Some of these choices are listed in Table A, which refers directly to the relevant product for the target grade.

Table B: Damage mechanisms

HYDROPROCESSING REACTORS

Production of cleaner fuels in accordance with current standards requires a refinery to use hydrotreating units to reduce sulfur, aromatics, nitrogen, oxygen, and metals while improving the combustion quality and smoke point of naphtha, diesel, and kerosene.

Hydrotreating / hydrodesulphurization (HDS) reactors are critical equipment in a hydrotreating unit.

In order to increase the refinery's yield rate, however, conversion units are needed to crack the vacuum gas oil (VGO) and the atmospheric gas oil (AGO) as well as the gas oil from the coker and the visbreaker units. This method enables the refinery to process the residual oil ("the bottom-of-the-barrel"). For example, hydrocracking is a catalytic cracking process that is assisted by the presence of hydrogen. In this case, hydrocracking reactors are the critical equipment.

The common element among hydroprocessing reactors of this type is the use of advanced 2.25Cr-1Mo-0.25V material, which has numerous merits over conventional grade material, including greater tensile strength at elevated temperatures,

enabling the industry to use reactors with lower wall thickness and weight (about 25% less weight). Additionally, it makes reactors less susceptible to damage mechanisms, such as temper embrittlement and high temperature hydrogen attack (HTHA) and last but not least, it provides stronger resistance to weld overlay disbonding induced by hot hydrogen.

Despite all these advantages, weld fabrication of reactors made of this grade of material ultimately becomes challenging due to various material sensitivities. e.g., weld cracking and re-heat cracking. Furthermore, intermediate and post-weld heat treatment as well as non-destructive examination (NDE) requires a different – and very precise – process compared to conventional 2.25Cr-1Mo grades. An example is the Time Of Flight Diffraction (TOFD) ultrasonic test.

Let's take a brief look at the welding of a hydroprocessing reactor:

B Nozzle welds -

Piping nozzles, instrumentation nozzles, as well as the hand holes are critical areas as they are the only openings of the reactor and must thereby withstand conditions within the reactor. The conventional method represents the use of the SMAW process for the nozzle welds, but experienced fabricators currently use single-wire SAW. Due to the especially restrained condition of the joint, ISR (intermediate stress relieving) is of paramount importance.

D Weld overlay

The usual overlay deposit for such reactors is S.S 347. Depending on the accessibility and the cladding area, different processes are chosen:

An important point to Cr-Mo 22V build up overlay is the necessity of ISR (intermediate stress relieving) due to restrained condition.

A Fabrication of the reactor shell

Depending on the design requirements and the wall thickness, shell material can be fabricated from plate or forged rings. If plates are used, they must be re-rolled and longitudinally welded to form a ring. A combination of both plate rings and forged rings is also possible, for example, forged rings for the quench zone and support skirt and plate rings for the rest of the shell arrangement. Narrow gap submerged arc welding (SAW), either with tandem or single wire, is the process of choice. With our wire/flux combination and the corresponding parameter setting, it is feasible to have the smallest possible opening, which significantly reduces the consumption of filler metals and welding time. A smaller amount of GTAW rod and SMAW electrode is also deposited.

Longitudinal Joints: ASME SA542 Gr. D CL 4a. ASME SA832 Gr. 22V

Circumferential Joints: - - - - -

Forged rings: ASME SA336 Gr. F22V

Plate-fabricated rings: ASME SA832 Gr. 22V or ASME SA542 Gr. D, CL 4a

Shell to dished end / dished end to support welds

Heads are either single-piece or multi-piece welded. Precise joint alignment is also needed as the dished end has a lower wall thickness compared to the shell. If forged profiles are used, skirt to bottom is sometimes a single forged piece.

E Heat treatment

DHT: Dehydrogenation heat treatment of 350° C for 4 hours is essential to minimize the susceptibility to cold cracking due to residual hydrogen in the weld. **ISR:** Intermediate stress relieving is necessary, especially for highly restrained joints such as nozzle welds. The recommended temperature for ISR is 650 – 670° C for 4 hours to ensure a partial elimination of the residual stresses in the weld. **PWHT:** Post weld heat treatment for CrMo-22V has a very narrow tolerance in comparison to conventional steel grades. The recommended PWHT is 705° C for 8 hours.

Max PWHT: Several heat treatments are applied during fabrication, including DHT, ISR, and final PWHT. Sometimes, repairs are undertaken during fabrication. An additional cycle should be planned for any necessary repairs after installation. A maximum PWHT condition, which has an equal effect of all previously cited PWHT cycles, must be simulated. To that end, and to define one PWHT condition that covers all cycles, the Hollomon parameter (HP) of all the PWHTs should be calculated and then for any given time a PWHT temperature can be calculated vice versa.

 $HP = (273^{\circ}C + T) \times (20 + log10(t/60)) 10-3$

 $T = 103 \text{ HP/(20 + log10(t/60))-273}^{\circ}\text{C}$

 $t = 60 \times 10(1000 \text{ HP/}(273^{\circ}\text{C} + \text{T})-20)$

Step cooling: is done to simulate an accelerated embrittlement for evaluation of potential temper embrittlement.

F Reheat cracking and tramp elements

Since introduction of this material, the industry has encountered many difficulties due to reheat cracking after PWHT. With precisely controlled amount of the tramp elements (Typical X factor: 8 and typical K factor: 0.7), the reheat cracking problem is under control.

ASME BPVC Section VIII Division 2, API RP 934A, API RP582, ASTM G146-01

GAS PROCESSING

In the form it is extracted, natural gas cannot be used as fuel or feedstock. It needs to be treated in gas processing plants. Irrespective of whether a gas processing plant is constructed for a specific gas field or inside a refinery to process refinery gases, it generally contains:

The global gas resource landscape has changed significantly within the past decade. Unconventional gas, so called either due to its quality (sour and ultra-sour gas) or its source (shale gas, coal gas), has begun to play an important role. As such, there is a need for different solid or weld overlaid corrosion resistance alloys in different separators and fractionators. Examples are the injection lines, inlet separators, and slug catcher manifold / drums in which – depending on the sourness of the gas – S.S 316L, Alloy 825, or Alloy 625 weld overlay is applied.

Selection of the base material can also vary depending on the operating pressure or job site temperature. Use of carbon steel as well as low alloy / chrome-molly alloys is possible depending on the operating conditions.

Inlet facilities: To separate natural gas from water and impurities. These facilities can

also include slug catcher manifold/drum

Pre-treatment: To remove sulfur, H2O, Hg, and CO₂ from natural gas **Fractionation:** To fractionate different gaseous and NGL hydrocarbons

OLEFINS AND AROMATICS

Olefins (such as Ethylene and Propylene) and Aromatics (Benzene, Toluene, and Xylene) are key products in the petrochemical industry. Naphtha from the oil refinery enters the cracking furnace and is cracked by being heated to 1,150°C. The cracked hydrocarbon enters the quench oil / water columns. The gases are then compressed and liquefied in different temperatures down to -150°C.

A cracker furnace represents the heart of a plant (a description follows on the next page). voestalpine Böhler Welding draws upon many years of experience in the production of filler metals for welding the cracker furnace tubes. A plant has both high-temperature parts and low-temperature areas. Various hydocarbons have very low boiling temperatures and therefore, low-temperature steels grades are needed for transport and storage of these materials within the plant. Some cryogenic products are listed in the products table of this brochure. However, all the LPG- and LNG-related products are separately described in our LNG/LPG brochure.

In Table F, we have listed some of the critical process equipment in an Olefin / Aromatic plant. A number of the major damage mechanisms from typical olefins/aromatics are listed in Table G. Some of these damage mechanisms can be controlled by selecting high-quality base material and welding consumables.

WELDING OF REFORMER AND CRACKER TUBES

In petroleum refining, there is the demand for a steam / catalytic reforming process that reforms the hydrocarbon molecule to a desired shape. This process is also used for hydrogen production in the hydrogen unit of large-scale refineries, where very large amounts of process hydrogen are needed. The operating temperature can exceed 900°C.

In petrochemical plants, e.g., in Olefin and Aromatic plants, naphtha from the refinery first enters into a cracker, the heart of the plant. The temperature in the cracker furnace can exceed 1,150°C. The cracking process leaves coke on the tube walls, which results in higher temperatures that can reach the operational limits.

In both of the above-mentioned applications, centrifugally cast tubes represent the main element of the process. The tubes and the respective welded joints must be able to withstand numerous damage mechanisms, including but not limited to creep / stress rupture, carburization, and fatigue. Being able to balance increased strength, higher creep resistance, and greater toughness has been a challenge for the industry.

Over decades, the industry has benefited from the introduction of new alloys with various Cr and Ni content and the addition of alloying elements, such as Si, Ti, Zr, Nb, Mo, Co, etc. to create the ability to withstand higher operating

temperatures and, at the same time, to reach reasonable creep strength and carburization resistance.

Over-alloyed welding consumables have always been available in our portfolio, but similar or matching consumables for every new tube grade have been what we offer in order to minimize the difference between the thermal expansion coefficient in the weld joint and the tube; this enables a longer life cycle of the welded tubing.

A list of the main products for the welding of furnace tubes is provided in the product section of this brochure.

JOIN! voestalpine Böhler Welding

With over 100 years of experience, voestalpine Böhler Welding is the global top address for the daily challenges in the areas of joint welding, repair, hardfacing and cladding as well as brazing. Customer proximity is guaranteed by more than 40 subsidiaries in 25 countries, with the support of 2,200 employees, and through more than 1,000 distribution partners worldwide. With individual consultation by our application technicians and welding engineers, we make sure that our customers master the most demanding welding challenges. voestalpine Böhler Welding offers three specialized and dedicated brands to cater our customers' and partners' requirements.

Lasting Connections – As a pioneer in innovative welding consumables, Böhler Welding offers a unique product portfolio for joint welding worldwide. More than 2000 products are adapted continuously to the current industry specifications and customer requirements, certified by well-respected institutes and thus approved for the most demanding welding applications. As a reliable partner for customers, "lasting connections" are the brand's philosophy in terms of both welding and people.

Tailor-Made Protectivity™ – UTP Maintenance ensures an optimum combination of protection and productivity with innovative and tailor-made solutions. Everything revolves around the customer and their individual requirements. That is expressed in the central performance promise: Tailor-Made Protectivity™.

In-Depth Know-How – As a leading brand of soldering and brazing consumables, Fontargen Brazing offers proven solutions based on 50 years of industrial experience, tried and tested processes and methods. This In-Depth Know-How has made Fontargen Brazing an internationally preferred partner for every soldering and brazing task.

The Management System of voestalpine Böhler Welding Group GmbH, Peter-Mueller-Strasse 14-14a, 40469 Duesseldorf, Germany has been approved by Lloyd's Register Quality Assurance to: ISO 9001:2015, ISO 14001:2015, OHSAS 18001:2007, applicable to: Development, Manufacturing and Supply of Welding and Brazing Consumables.
